

Preliminary and partial presentation of

GLACIER INVENTORY

Southern Norway

THE NORWEGIAN WATER RESOURCES AND ELECTRICITY BOARD

GLACIOLOGY SECTION

1969

PREFACE

Various attempts have been made to determine the total area covered by "permanent snow and ice" in Norway. Most of this work was based upon old maps at a scale of 1:200 000 or smaller, which in connection with the bad cartographic representation of high-mountain areas, gave results of doubtful value for scientific purposes.

The best inventory to date was made by O. Liestøl about 1960; the result is published as a "List of the areas and number of glaciers" in Hoel and Werenskiold (1962, p. 35-54).

For engineering purposes, particularly for the modern planning of hydro-electric power stations in mountain areas it is necessary to take into account the existence of glaciers when calculations are made of expected water discharge. During the last years more and more high-mountain drainage basins in Norway are being utilized for power production, and, as melt water from glaciers contribute significantly to the river discharge, it is obviously of great importance to have adequate knowledge about the glacier areas and the glacier mass balance.

For this reason detailed glacio-hydrological investigations were started in Norway in 1962 (Østrem 1964). They generally comprise mass-balance measurements, meteorological observations, ice movement studies, river discharge and sediment transport measurements. The work is carried out at a limited number of selected glaciers that are considered representative for certain mountain basins. To extend the hydrological results from these investigations to other glacierized areas, it is necessary to know the exact location and size of all glaciers in the area.

Therefore, a detailed glacier inventory was started in January 1969. The present publication was prepared to demonstrate the methods and to give some preliminary results for further discussion

LITERATURE

INTRODUCTION TO INVENTORY OF SURFACE SNOW AND ICE IN SOUTH NORWAY

Present stage of inventory

Work is presently nearing its completion on a detailed inventory of surface snow and ice in South Norway. The following presentation of maps and tables constitute the first part of the inventory and give details on glaciers and glacierettes that contribute to the river systems draining eastwards in South Norway. In addition a map and some tables with particulars of Jostedalsbreen are presented.

Source material for the inventory

Earlier suggestions for guides to similar types of inventories that have come forward under The International Hydrological Decade have provided valuable guidelines for the work at hand. (Müller 1969, Ommannet et. al. 1969).

The source material for the inventory has been existing topographical map series in scales 1:50 000 and 1:100 000 together with aerial photographs.

The AMS M717 map series, scale 1:50 000, have mainly been used in the registration and for the associated measurements. In certain cases, special glacier maps and local maps existed and they have then been used. It should be pointed out that the 1:50 000 series differ in quality between individual map sheets because some of these maps are based on enlargements of maps from old plane-table surveys at a scale of 1:100 000, while others are a result of modern high-accuracy photogrammetric construction. In the North-Western part of South Norway there are glacierized areas where no reliable maps are available.

In order to make the basic source material more homogeneous and reliable, the information about snow and ice shown on the maps was revised by simple construction methods from available aerial photographs taken in the period 1958 - 68. In a few cases where this coverage was insufficient, copies from the 1955 AMS South Norway photography were used. This revision of snow and ice information was carried out

by means of a pentaprism, The Zeiss LUZ Aero-Sketchmaster.

Although the basic map material thus has been improved, differences of quality in the source material still exist and this is reflected in the accuracy ratings of individual measurements as shown in the tables. The recognition of what is, and what is not, glacier or perennial snow-field, is generally a matter of subjective judgement. To some extent it also depends on the quality of the photography. Index maps giving detailed information about source material will accompany the final presentation of the inventory.

Storing of the obtained data

The measured data has been stored on punch cards to facilitate further processing of the obtained measurements. Each individual glacier, glacierette or subdivision of a larger glacier has its related information on one punch card. Hence, one card represents one identified unit in the inventory. Ice-caps and glaciers with common accumulation areas are represented by more than one card.

Organization and presentation of data.

The accompanying tables are direct outprints of the punch cards. Each table is accompanied by a 1:250 000 glacier map for reference. These maps can further be related to the 1:250 000 AMS 515 series which cover all of Norway, for reference to other detail than glaciers.

Drainage basins as reference areas for the inventory.

The individual glaciers, glacierettes and subdivisions of larger glaciers are in the inventory organized numerically in relation to the natural drainage basin to which they contribute with their meltwater. Drainage diversions due to hydro-electric power development etc. are thus not considered in the inventory, but only referred to by subnotes in the tables, and by symbols on the maps. Each unit is allotted a number between 0 and 99. The numbering begins with the unit nearest to the outlet of the basin on the right hand side of the direction of flow. Rising numbers then follow clockwise for each identified unit

along the drainage system. If a drainage system contains more than 99 units it is subdivided into smaller basins of favourable size, and numbers are allotted similarly.

Special presentation of large composite glaciers.

In special cases larger glaciers were subdivided and presented only partially because they drain through several separate individual basins. It is the intention, however, to repeat details of the composite glaciers (and ice-caps) in the form of a summary table where all the components of the larger unit will appear together. The Jostedalsbreen table is shown as a sample in the present volume.

Explanation to the tables and brief remarks about measurements.

<u>Column heading</u>	<u>Comments</u>
BASIN IDENT	<p>This is a first and so far undeveloped attempt of a numerical drainage basin identification system. In the "Vassdragsregister" of the Norwegian Water Resources and Electricity board, every major drainage basin with outlet to the sea has been allotted a number. The numbering starts in the south at the Swedish border; rising numbers follow clockwise along the coast. Stretches of coastline with minor streams have been allotted similar numbers.</p> <p>The system can be developed further to identify sub-basins as suggested in earlier mentioned guides to snow and ice inventories.</p>
WATER GAUGE No.	The glacier unit is here related to the identification number of the nearest water gauge downstream from the glacier in the drainage system. These are also displayed on the glacier index map.
GLAC. No.	The numbers identify the glacier units in the drainage system and are of special value

for cross reference between columns in the table and glaciers plotted on the glacier index map.

GLAC. NAME	The name of the glacier unit, or the name of the larger entity of which it may be a part, is quoted if it is known. In many cases an abbreviated form has been used.									
LONGIT AND LATIT	The longitude and latitude of a near central point of the glacier is quoted with an average accuracy of 10".									
UTM	The glacier unit is related to the one-km square of the Universal Transverse Mercator reference system, in which it is situated (or, for larger glaciers, the square that is located at its centre).									
ORIENTAT	The orientation of the main area of exposure of the accumulation and ablation areas, respectively, are quoted in one of the 8-point compass directions.									
ELEVATIONS M A S L	These columns refer to parameters defined by elevations in metres above sea level for each measured unit. The parameters are:									
HIGH LOW	The highest and lowest altitude of the glacier unit as measured from the revised map. An accuracy rating (AR) accompanies each set of measurements.									
A R	The AR (accuracy rating) is specified with a value, the significance of which is stated below:									
	<table border="0"> <tr> <td>1. Excellent</td> <td>Error</td> <td>0-25 m</td> </tr> <tr> <td>2. Good</td> <td>"</td> <td>25-50 m</td> </tr> <tr> <td>3. Fair</td> <td>"</td> <td>50-100 m</td> </tr> </table>	1. Excellent	Error	0-25 m	2. Good	"	25-50 m	3. Fair	"	50-100 m
1. Excellent	Error	0-25 m								
2. Good	"	25-50 m								
3. Fair	"	50-100 m								

- | | | | |
|----|------------|-------|------------|
| 4. | Acceptable | Error | 100-200 m |
| | 5. | " | over 200 m |

TSL	Where it has been possible to identify the transient snow line from the aerial photographs, the measured elevation of this is quoted together with the day, month and year of photography, given in a 6-place number group. An accuracy rating is also given with the same error limits as above.
LENGTH	This parameter is quoted in kilometers and refers to the length of the glacier along its line of flow. The listed length is often unreliable since the irregular shape of many glaciers lead to ambiguities. Furthermore, the measurements were generally made on maps that, of course, give only the horizontal projection of glacier length.
REMARKS	A special standardized remarks-code has been used, the key is presented below:
M U	<u>Map unreliable</u> in the area where the glacier is, or should be, displayed.
P S F	<u>Possible Snow Field</u> . It is often hard to decide whether a certain area is a large snow field or a real glacier. Evidence of movement (crevasses, silty melt water etc.) may be obscured, so PSF is then indicated.
B	The measured unit is the lower part of an interrupted (regenerated) glacier <u>below</u> the main glacier.
W S	The glacier is situated on a <u>Water Shed</u> and drains in more than one direction. (The quoted accumulation area orientation is a mean direction of exposure).
S W S	The measured unit is a <u>Subdivision</u> of a larger glacier unit.

J B	The measured unit is a Subdivision of the <u>Jostedalsbreen</u> Ice Cap.																
H J	The measured unit is a Subdivision of the <u>Hardangerjøkulen</u> Ice Cap.																
SPEC INVESTIG	The measured unit is subject to special investigations (i. e. mass balance measurements, etc.)																
AREA	<p>The areas of the glacier units have been measured with a ordinary planimeter and are given in square kilometers. The quoted values for the areas refer, as far as possible, to the area of active ice. A reservation must be made as an exact identification of this active area was in many cases very difficult. It should also be noted that the given area is the horizontal projection of an irregular surface. An accuracy rating (AR) accompanies each measurement and is specified with a figure that has the following meaning:</p> <table border="0"> <tr> <td>1. Excellent</td> <td>Error</td> <td>0-5%</td> </tr> <tr> <td>2. Good</td> <td>"</td> <td>5-10%</td> </tr> <tr> <td>3. Fair</td> <td>"</td> <td>10-15%</td> </tr> <tr> <td>4. Acceptable</td> <td>"</td> <td>15-25%</td> </tr> <tr> <td>5. Unreliable</td> <td>"</td> <td>over 25%</td> </tr> </table>		1. Excellent	Error	0-5%	2. Good	"	5-10%	3. Fair	"	10-15%	4. Acceptable	"	15-25%	5. Unreliable	"	over 25%
1. Excellent	Error	0-5%															
2. Good	"	5-10%															
3. Fair	"	10-15%															
4. Acceptable	"	15-25%															
5. Unreliable	"	over 25%															
	1. Excellent	0-5%															
	2. Good	5-10%															
	3. Fair	10-15%															
	4. Acceptable	15-25%															
	5. Unreliable	over 25%															

Summary Tables

Besides the outprints from the puch cards, two summary tables for two selected areas, Bøvra drainage basin and Jostedalsbreen ice-cap, are shown in this publication.

In Table 1 it is listed all river discharge stations in the basin (first column) and their individual drainage areas (second coumn). The glacierized areas have been added for each discharge station and the sum is

presented in the third column. Finally, the percentage of glacier coverage is computed for each discharge station and given in the last column.

Because present information is incomplete for some water gauges the last column may be misleading. It is, however, included here to show the intended use of the collected glacier data for this kind of computation which is of direct practical importance for engineering purposes.

NOTE: In cases where the drainage area for a discharge station is not yet known, the figure "100.00" (sq. km) is provisionally plotted in the table.

In Table 2 the number and total area of all glaciers with equal ablation area orientation are listed. This makes 8 sums which then have been computed as percentages of the total glacierized area in the basin under consideration (or for the ice cap).

Final remarks.

The present inventory is of a relatively simple nature. However, it provides a framework that can be extended further. Summaries of data and some additional analyses will definitely be carried out before the material is finally published, whereas morphological classification and description of glaciers as suggested by Müller (1969) may be a future step.

GLACIER INVENTORY - SOUTHERN NORWAY

SUMMARIES

JOSTEDALSPREEN

NUMBER OF SUBDIVISIONS 44
 NUMBER OF QUOTED WATER GAGES 12

TOTAL GLACIER AREA 475.61 KM²

TABLE 1
 =====

WATER GAGES, THEIR TOTAL DRAINAGE-AREAS AND GLACIER-COVERED AREAS

WATER GAGE-NO	AREA KM ²	TOTAL GLACIER AREA KM ²	GL AREA IN PER CENT OF WG AREA
1071	100.00	16.00	16.00
1405	100.00	48.00	48.00
1408	100.00	47.03	47.03
1121	100.00	77.67	77.67
613	366.00	66.35	18.13
1532	100.00	12.38	12.38
1556	100.00	8.2	8.20
617	367.00	12.60	3.43
932	569.00	23.75	4.17
621	210.00	58.38	27.80
622	260.00	42.69	16.42
1678	100.00	23.84	23.86
SUM OF SUBDIVISIONS WITHOUT WATER GAGES			2

TABLE 2
